## 1 Introduction

This document is designed to provide new users of L<sup>A</sup>T<sub>E</sub>X with a reference for the local features not documented in the manual (*The L<sup>A</sup>T<sub>E</sub>X Book*, Lesley Lamport, Addison Wesley 1987); it takes the place of the *Local Guide* referred to in the book. For a general introduction to L<sup>A</sup>T<sub>E</sub>X, you are referred to the companion manual *Essential L<sup>A</sup>T<sub>E</sub>X ++*, mostly by Jon Warbrick. For a general introduction to the concepts of the T<sub>E</sub>X software distribution, see Joachim Schröd’s *Components of T<sub>E</sub>X*.

Readers of this document will normally be staff or students who have either taught themselves L<sup>A</sup>T<sub>E</sub>X, or are being taught it as part of a course. Completely new users should read *Essential L<sup>A</sup>T<sub>E</sub>X*

++ first, to familiarize themselves with basic concepts. Most of this manual is for reference purposes, so do not read it as a tutorial text!

L<sup>A</sup>T<sub>E</sub>X runs on a variety of computers at many different sites. This document tells you how to use L<sup>A</sup>T<sub>E</sub>X on Unix computers.<sup>1</sup> It is not about L<sup>A</sup>T<sub>E</sub>X itself, which is described by the manual—*L<sup>A</sup>T<sub>E</sub>X: A Document Preparation System*, published by Addison-Wesley, available at the book shop.

If you have a question that you can't answer by reading the manual and this document, ask the local support team.

## 2 Getting Started

### 2.1 Running a Sample File

Before preparing your own documents, you may want to get acquainted with L<sup>A</sup>T<sub>E</sub>X by running it on a sample input file. First make your own copy of the file `sample.tex` by typing the following command:

```
cp /usr/local/tex/texmf/tex/latex/base/sample2e.tex .
```

(You must type the space followed by the period at the end. This and all other commands are ended by typing *return*.) A copy of the file `sample.tex` is now in your current directory; you can edit it just like any other file. If you destroy or mess up your copy, typing the above command again gets you a fresh one. Study this file as an example of a complete L<sup>A</sup>T<sub>E</sub>X document, which uses many of the common features.

Next, run L<sup>A</sup>T<sub>E</sub>X on the file `sample.tex` by typing:

```
latex sample
```

When L<sup>A</sup>T<sub>E</sub>X has finished, it will have produced the file `sample.dvi` in your directory. You can print this file by typing the command

```
dvips sample
```

After it has been printed, you can delete `sample.dvi`. You'll also see a file called `sample.log` which contains a copy of all the messages that came on the screen (with, sometimes, more detail). You can safely delete this after your run.

### 2.2 Preparing and Running L<sup>A</sup>T<sub>E</sub>X on Your Own Files

You can use any text editor which produces plain ASCII text files to prepare input for L<sup>A</sup>T<sub>E</sub>X. The easiest way to start learning about L<sup>A</sup>T<sub>E</sub>X is by examining the file `small2e.tex` with your text editor. You can obtain your own copy of this file, in your directory, by typing the command

```
cp /usr/local/tex/texmf/tex/latex/base/small2e.tex .
```

After you have prepared your file, whose name should have the extension `tex`, you must run it through L<sup>A</sup>T<sub>E</sub>X and print the output. Follow the instructions in Section 2.1, except substitute the first name of your file for `sample`. Remember to save disk space by deleting the `dvi` files after printing the output.

If you are used to using an Emacs-type editor, you may wish to utilise the facilities provided by GnuEmacs. These can be used on ordinary terminals, but if used on a workstation console, can use the mouse and function keys. Look out for the AUC-TeX package which provides a comprehensive set of facilities for editing L<sup>A</sup>T<sub>E</sub>X code.

---

<sup>1</sup>Excellent public domain implementations of T<sub>E</sub>X for MSDOS, OS/2 and Macintosh computers are available from the UK T<sub>E</sub>X Archive; see A.1 below.

<i>Question</i>	<i>Answer</i>
How do I run L <sup>A</sup> T <sub>E</sub> X	Use the ‘ <code>latex</code> ’ command...
How do I print a file?	Use the <code>dvips</code> command...
Can I have bibliographies done for me?	Use BIB <sub>T</sub> E <sub>X</sub> (it’s documented in the L <sup>A</sup> T <sub>E</sub> X book Appendix B!)—see section 5 below.
How do I recover from errors?	T <sub>E</sub> X is notorious for giving you apparently meaningless error messages! If you type ‘e’ when you get a T <sub>E</sub> X ‘?’ prompt, you will be put into the editor (by default, ‘vi’—set the environment variable <code>TEXEDITOR</code> to use a different one) at the error-producing line.
What if I run out of T <sub>E</sub> X memory?	This is a very big T <sub>E</sub> X already that you are running. If you run out of memory, it’s probably your fault.
Is it possible to draw pictures?	L <sup>A</sup> T <sub>E</sub> X itself has a ‘ <code>picture</code> ’ environment, described in the manual, but the simplest way is to include a POSTSCRIPT figure created with any good drawing tool (see section 3.2.1 below for how to include POSTSCRIPT in L <sup>A</sup> T <sub>E</sub> X).
How do I preview files before I print them?	Use one of two previewers, <code>dvipage</code> and <code>xdvi</code> , depending on whether your windowing system is Sunview or X Windows.
Are there other packages for L <sup>A</sup> T <sub>E</sub> X?	Lots. We have tried to collect useful-looking things. Some of these are documented below.
Are we in contact with the rest of the L <sup>A</sup> T <sub>E</sub> X community?	Yes. There is a world-wide T <sub>E</sub> X-hackers mailing list, and a UK list. These are the next line of defense after your local gurus; the UK bulletin is posted on Usenet news.
Are there other macro packages than L <sup>A</sup> T <sub>E</sub> X?	Yes, certainly, but do not expect as much documentation and examples. $\mathcal{A}\mathcal{M}\mathcal{S}$ -T <sub>E</sub> X (from the American Mathematical Society) is widely used. Such formats are not available by default—talk to technical support if you want to use them.
Can I use Metafont to create my own fonts?	Yes, it is installed. But don’t expect much help about design!
Can I join a T <sub>E</sub> X User Group?	Yes, contact the T <sub>E</sub> X Users Group, P. O. Box 869, Santa Barbara, CA 93102, USA. telephone 805-899-4673; email Internet : <code>tug@tug.org</code>

Table 1: Common questions, with answers

If you want to stop  $\LaTeX$  in the middle of its execution, perhaps because it is printing a seemingly unending string of uninformative error messages, press *Ctrl-C*, and respond to the prompt with ‘X’

## 3 Carrying On

### 3.1 Operating system issues

The only special problems in using  $\LaTeX$  under this operating system involve the way files are handled. The first problem arises because, when a program starts to write a file, the previous version of that file is destroyed. Thus, if an error forces you to stop  $\LaTeX$  prematurely (by typing *Ctrl-C*), then the files that  $\LaTeX$  was writing are incomplete, and the previous complete versions have been destroyed. You probably don’t care about the output on the *dvi* file, but, if you are making a table of contents or using cross-referencing commands, then  $\LaTeX$  also writes one or more *auxiliary files* that it reads the next time it processes the same input file. If the auxiliary files are incomplete because  $\LaTeX$  was stopped before reaching the end of its input file, then the table of contents and cross-references will be incorporated the next time  $\LaTeX$  is run on the same input file. You will have to run  $\LaTeX$  a second time to get them right. If you want to avoid having to run  $\LaTeX$  twice after making an error—for example, if your input is very long—then you should save copies of these auxiliary files before running  $\LaTeX$ . An input file named *myfile.tex* and all the auxiliary files produced by  $\LaTeX$  from it are included in the file specifier *myfile.\**. Use the *cp* command to save copies of these files.

The second problem in using  $\LaTeX$  involves the files that  $\LaTeX$  reads. The file whose name you type with the *latex* command is called the *root file*. In addition to reading the root file,  $\LaTeX$  also reads the files specified by *\input* and *\include* commands. With our directory system,  $\LaTeX$  must know not only the names of these file but also on what directories they are. It will have no problem finding the correct files if you follow two simple rules:

1. Run  $\LaTeX$  from the directory containing the root file.
2. Keep all files specified by *\input* and *\include* commands in the same directory as the root file.

If you follow these rules, you never have to type a path specifier when using  $\LaTeX$ .

You should never break the first rule, otherwise  $\LaTeX$  will have trouble finding auxiliary files. (To run  $\LaTeX$  on someone else’s file, copy the file to your directory.) If you break the second rule, specifying a file from another directory in an *\input* or *\include* command, you must use a complete path name. For example, to include the file *hisfile.tex* from *kk*’s directory *foo/bar*, you can type

```
\include{/home/kk/foo/bar/hisfile}
```

For people who don’t like to obey rules, here is exactly how  $\LaTeX$  finds its files. The root file is found by the operating system according to its usual rules.  $\LaTeX$ ’s auxiliary files are read and written in the directory from which it is run. All file names specified in the  $\LaTeX$  input, including the names of document class files specified by the *\documentclass* command, are interpreted relative to the directory from which  $\LaTeX$  is run. If  $\LaTeX$  does not find a file starting in this directory, it looks in the system directory */usr/local/tex/texmf/tex/latex*. You can change the directories in which  $\LaTeX$  looks for its input files by setting the environment variable *TEXINPUTS*. You need to type a shell command:

Shell	command to type
rc	TEXINPUTS=(. /home/dracula/texdocs)
sh	TEXINPUTS=./home/dracula/texdocs:; export TEXINPUTS
csh	setenv TEXINPUTS ./home/dracula/texdocs:

This causes  $\LaTeX$  to look for files `!rst` in the current directory (do not neglect to specify a `.` for the current directory as the first place in the list), then in dracula's `texdocs` directory, and then in the system directory (the trailing `:` implies this). You might want to do this if your name is Dracula and you have your own personal package files in your `texdocs` directory.

## 3.2 How to use the `dvips` command

The `dvips` command is used to convert the  $\TeX$  output file into POSTSCRIPT, and spool it to a LaserWriter or other POSTSCRIPT printer (including screen-based POSTSCRIPT interpreters like GhostScriptor OpenWindows). It includes the facility to incorporate raw POSTSCRIPT files into  $\LaTeX$ , using a `\special` command (see below, section 3.2.1). It is normally configured to invoke `lpr` directly.

The `dvips` driver has a plethora of command line options. Reading through this section will give a good idea of the capabilities of the driver.

Many of the parameterless options can be turned off by immediately suffixing the option with a zero (0); for instance, to turn off page reversal if it is turned on by default, use `-r0`. The options that can be turned off in this way are `-a`, `-f`, `-k`, `-i`, `-m`, `-q`, `-r`, `-s`, `-E`, `-F`, `-K`, `-M`, `-N`, `-U`, and `-Z`.

This is a handy summary of the options; it is printed out when you run `dvips` with no arguments.

```
This is dvipsk 5.58a Copyright 1986, 1994 Radical Eye Software
Usage: dvips [options] filename[.dvi]
a*  Conserve memory, not time      y # Multiply by dvi magnification
b # Page copies, for posters e.g.  A   Print only odd (TeX) pages
c # Uncollated copies              B   Print only even (TeX) pages
d # Debugging                      C # Collated copies
e # Maxdrift value                 D # Resolution
f*  Run as filter                   E*  Try to create EPSF
h f Add header file                F*  Send control-D at end
i*  Separate file per section      K*  Pull comments from inclusions
k*  Print crop marks              M*  Don't make fonts
l # Last page                      N*  No structured comments
m*  Manual feed                    O c Set/change paper offset
n # Maximum number of pages        P s Load config.$s
o f Output file                    R   Run securely
p # First page                     S # Max section size in pages
q*  Run quietly                    T c Specify desired page size
r*  Reverse order of pages         U*  Disable string param trick
s*  Enclose output in save/restore V*  Send downloadable PS fonts as PK
t s Paper format                   X # Horizontal resolution
x # Override dvi magnification     Y # Vertical resolution
                                     Z*  Compress bitmap fonts

pp #-# First-last page
# = number   f = file   s = string   * = suffix, '0' to turn off
c = comma-separated dimension pair (e.g., 3.2in,-32.1cm)
```

The `-E` option makes `dvips` attempt to generate an EPSF file with a tight bounding box. This only works on one-page files, and it only looks at marks made by characters and rules, not by any included graphics. In addition, it gets the glyph metrics from the `tfm` file, so characters that lie outside their enclosing `tfm` box may confuse it. In addition, the bounding box might be a bit too loose if the character glyph has significant left or right side bearings. Nonetheless, this option works well for creating small EPSF files for equations or tables or the like.

### 3.2.1 Using the ‘epsfig’ package

If you want to include a POSTSCRIPT graphic into a L<sup>A</sup>T<sub>E</sub>X file, use the `\epsfig` package with, e.g.:

```
\documentclass{article}
\usepackage{epsfig}
```

Now, at the point you want to include the file, enter a line such as `\epsfig{figure=foo.ps}`. If your file did not (or does not currently) have a bounding box comment, you should supply it as in the following example:

```
\epsfig{bblx=100,bbly=100,bburx=500,bbury=500,file=foo.ps}
```

(in the same order they would have been in a normal bounding box comment). Note that all information for `\epsfig` is included in a single parameter, separated by commas. Now, save your changes and run T<sub>E</sub>X and `\dvips`; the output should have your graphic positioned at precisely the point you indicated, with the proper amount of space reserved.

The effect of the `\epsffile` macro is to typeset the figure as a T<sub>E</sub>X `\vbox` at the point of the page that the command is executed. By default, the graphic will have its ‘natural’ width (namely, the width of its bounding box). The T<sub>E</sub>X box will have depth zero and a ‘natural’ height. For graphics included with `\epsfig` where the size is given in T<sub>E</sub>X dimensions, this scaling will produce the correct, or expected, results.

You can enlarge or reduce the figure by putting `width=<dimen>` in the parameter of `\epsfig`. Then the width of the T<sub>E</sub>X box will be `\<dimen>` and its height will be scaled proportionately. Alternatively you can force the vertical size to a particular size with `height=<dimen>` in which case the height will be set and the width will be scaled proportionally. If you set both, the aspect ratio of the included graphic will be distorted but both size specifications will be honored.

By default, clipping is disabled for included EPSF images. This is because clipping to the bounding box dimensions often cuts off a small portion of the figure, due to slightly inaccurate bounding box arguments. The problem might be subtle; lines around the boundary of the image might be half their intended width, or the tops or bottoms of some text annotations might be sliced off. If you want to turn clipping on, just use the parameter `clip=` to `\epsfig`.

## 4 Document classes

The normal `article`, `book` and `report` classes described in the manual are available. There are three groups of *package* files available: a) those supplied with L<sup>A</sup>T<sub>E</sub>X, and endorsed by the maintainers; b) those initially developed by Frank Mittelbach and Rainer Schöpf (sometimes known as the ‘Mainz’ packages), and other members of the L<sup>A</sup>T<sub>E</sub>X team, which will definitely work; those written and distributed by other L<sup>A</sup>T<sub>E</sub>X users which have come into common use, but which are not so carefully tested. These packages may affect the main layout and style (eg ‘times’, ‘multicol’) or add new facilities (eg ‘longtable’).

### 4.1 ‘Mainz’ packages

The recent, widely-used, packages from Mittelbach and Schöpf have their own documentation, stored with the source of the packages in directories of the relevant name in `/usr/local/tex/texmf/tex/latex/tools`.

If you want to read the full documentation, copy the files from the relevant directory, and look at the *readme* file for how to get a printout. The packages are:

**array** An extensive revision of the L<sup>A</sup>T<sub>E</sub>X tabular and array modes by Frank Mittelbach; the chief differences are new options in the preamble, listed in Table 2, quoted from the documentation.

<code>m{width}</code>	Defines a column of width <code>width</code> . Every entry will be centered in proportion to the rest of the line. It is somewhat like <code>\parbox{width}</code> .
<code>p{width}</code>	Equivalent to <code>\parbox[t]{width}</code> .
<code>b{width}</code>	Coincides with <code>\parbox[b]{width}</code> .
<code>&gt;{decl.}</code>	Can be used before an <code>l</code> , <code>r</code> , <code>c</code> , <code>p</code> , <code>m</code> or a <code>b</code> option. It inserts <code>decl.</code> directly in front of the entry of the column.
<code>&lt;{decl.}</code>	Can be used after an <code>l</code> , <code>r</code> , <code>c</code> , <code>p{. . .}</code> , <code>t{. . .}</code> or a <code>b{. . .}</code> option. It inserts <code>decl.</code> right after the entry of the column.
<code> </code>	Inserts a vertical line. The distance between two columns will be enlarged by the width of the line in contrast to the original definition of $\LaTeX$ .
<code>!{decl.}</code>	Can be used anywhere and corresponds with the <code> </code> option. The difference is that <code>decl.</code> is inserted instead of a vertical line, so this option doesn't suppress the normally inserted space between columns in contrast to <code>@{. . .}</code> .

Table 2: The new preamble options for ‘array’

Additionally there is a new parameter called `\extrarowheight`. If it takes a positive length, the value of the parameter is added to the normal height of every row of the table, while the depth will remain the same. This is important for tables with horizontal lines because those lines normally touch the capital letters.

Facilities are available for defining new column specifiers, and for columns which line up on a decimal point.

This package also provides a ‘longtable’ package which implements arbitrarily-long multi-page tables. For simple multi-page tables, the *supertab* package described below in section 4.2 will probably suffice.

**ftnright** a package which sets footnotes in the right-hand column of a two column style.

**multicol** Provides a flexible mechanism for multiple columns on a page. An environment `multicols` is provided, with a parameter of the number of columns desired. The number of columns (up to 10) can be changed in the middle of a page.

<p>This is set in four columns across the page, and ‘multicols’ is going to take care of the column breaks and making the columns the same height. You</p>	<p>can see that the normal justification of <math>\TeX</math> is ending this hard work.</p> <p>What is that sound high in the air Murmur of maternal</p>	<p>lamentation Who are those hooded hordes swarming Over endless plains, stumbling in cracked earth Ringed by the flat horizon only</p>	<p><b>What is the city over the mountains</b> <i>Cracks and reforms and bursts in the violet air</i> Falling towers</p>
--	--	---	---

**theorem** new implementations of theorem environments.

**verbatim** new, more robust, implementations of verbatim environments, including facilities for verbatim input of a text file.

Some of these documents are rather technical. Ask for advice if you do not understand them.

## 4.2 Other packages

Some commonly-used, or interesting, packages which change the normal layout or style, or add new facilities, are

**pifont** Gives you access to Zapf Dingbats, *if you have a PostScript printer and use dvips*.

- \* `\ding` generates a Zapf Dingbat character; it has a parameter of the Dingbat number (see chart p. 14 below). Thus `\ding{166}` generates ☺.
- \* `\dingfill` (with the usual numeric parameter) acts like other filling commands, but fills the space with a chosen Dingbat ☺ ☺ ☺ ☺ ☺ ☺ ☺ ☺ like that.
- \* `\dingline` generates a freestanding line of the little chaps:  

- \* Inevitably, the ‘dinglist’ environment sets up an itemized list, but has a Dingbat instead of a bullet (you are reading a `dinglist` at the moment).

**rotating** This package provides three new environments.

‘Rotate’ provides a generalised rotation environment, where the text will be rotated (clockwise, as is normal in POSTSCRIPT) by the number of degrees specified as a parameter to the environment, but no special arrangement is made to find space for the result. Note the % at the end of `\begin{rotate}{56}` — this is vital to prevent a space getting into the rotated text.

Start here → End here

```
Start here
  \begin{rotate}{56}%
    Save whales
  \end{rotate}
End here
```

A complete example of rotating text without leaving space would be the ‘Save the whale’ text written at 10 degree intervals round the compass. We use ‘rlap’ to ensure that all the texts are printed at the same point. Just to show that T<sub>E</sub>X can handle POSTSCRIPT muckings-about properly...

```
\newcount\wang
\newsavebox{\wangtext}
\newdimen\wangspace
\def\wheel#1{\savebox{\wangtext}{#1}%
\wangspace\wd\wangtext
\advance\wangspace by 1cm%
\centerline{%
\rule{0pt}{\wangspace}%
\rule[-\wangspace]{0pt}{\wangspace}%
\wang=-180\loop\ifnum\wang<180
\rlap{\begin{rotate}{\the\wang}%
\rule{1cm}{0pt}#1\end{rotate}}%
\advance\wang by 10\repeat}}
\wheel{Save the whale}
```

<p>The following list is like <code>description</code>, but the labels are set in a wider box:</p> <p><b>cats and bears</b>  are jolly good creatures to make money from, if you draw greetings cards</p> <p><b>vultures</b>  seldom appear on any cards</p> <p><b>beas, ticks, mites and cockroaches</b>  have no credibility at all, though they do appear occasionally in literature, most famously in the case of ‘archie and mehitabel’</p>
--

Figure 1: Demonstration of catalogue environment

If the user desires  $\LaTeX$  to leave space for the rotated box, then ‘turn’ is used:

Start here	end here	Start here <code>\begin{turn}{-56}%</code>
		Save the whale
		<code>\end{turn}</code> end here

*Save the whale*

The environment ‘Sideways’ is a special case, setting the rotation to  $-90$ , and leaving the correct space for the rotated box.

Start here	End here	Start here
		<code>\begin{sideways}%</code>
		Save the whale
		<code>\end{sideways}</code>
		End here

*Save the whale*

### 4.3 Local macros and environments

A number of useful macros and environments are provided in a single file `local.sty`, which is read in by the ‘`localart.sty`’ style. It defines (at least) the following commands:

- `catalogue` is a new environment for lists, demonstrated in Fig. 1.
  - `widedesc` is a new environment for lists, demonstrated in Fig. 2.
  - `screen` is a new environment for quoting code, demonstrated in Fig. 3. The text is set in a verbatim frame to make it stand out.
  - Leslie Lamport’s `alltt` environment is provided, which is like `verbatim` except that the `\`, `{` and `}` characters remain active, permitting you to change font etc
- In addition, all the names of  $\TeX$ -related products are provided as macros, listed in Table 3.

## 5 Additional $\BIB\TeX$ style files

In addition to the ‘plain’ and ‘alpha’ style files for  $\BIB\TeX$  described in the  $\LaTeX$  book, a number of other style files are available:

**acm** generates the style suitable for submission to the ACM

The following list is like `description`, but the labels are set in a wider box:

**cats and bears** are jolly good creatures to make money from, if you draw greetings cards

**vultures** seldom appear on any cards

**bees, ticks, mites and cockroaches** have no credibility at all, though they do appear occasionally in literature, most famously in the case of ‘archie and mehitabel’

2.073	622	3110	20
2.488	746	3732	24

Table 4: Relationship between fontsize conventions

**ieeetr** generates style for IEEETR

**apalike** is a generic ‘natural science’ style that is essentially Harvard. You must use package `apalike` if you intend to use this bibliography style.

## 6 Fonts

A very large number of fonts are available to you, both ones generated by METAFONT, which should be available anywhere, and the POSTSCRIPT ones if you have a POSTSCRIPT printer (see 6.1 below). In case you are curious about the relationship between magnification, point size, file name etc, Table 4 may help.

### 6.1 Using POSTSCRIPT fonts

A number of special packages are available if you know that output is going to a POSTSCRIPT printer: for instance, using package `palatino` will make L<sup>A</sup>T<sub>E</sub>X use Palatino for Roman, Avant Garde for Sans Serif, Courier for Typewriter. Similar packages are available for Times (`times` package), New Century Schoolbook (`newcen`). In general POSTSCRIPT fonts are to be preferred, since the Computer Modern Roman fonts do not reproduce well on a 300 dpi LaserWriter. You should *not* use the DVI output files on other systems or send them to other sites; the original L<sup>A</sup>T<sub>E</sub>X source is, however, totally standard, and can be happily distributed to other T<sub>E</sub>X users (who will simply get the CMR fonts when they print by removing the package). **BEWARE** that you may get problems if you use a lot of mathematics: the maths fonts were designed to go with Knuth’s Computer Modern Roman, and may not look good with Palatino or Times. You are recommended to consider using pure Computer Modern Roman if you are a heavy maths user, or purchase the Lucida Bright and Lucida New Math, or MathTime, fonts.

Examples of common POSTSCRIPT typefaces are:

- Family pag (AvantGarde)

ptmWhat is that sound high in the air  
Murmur of maternal lamentation  
Who are those hooded hordes swarming  
Over endless plains, stumbling in cracked earth  
Ringed by the sad horizon only

Table 5: Names for common POSTSCRIPT fonts in T<sub>E</sub>X

*Cracks and reforms and bursts in the violet air*  
*Falling towers*

One particular font is more difficult to use, the collection of symbols called Zapf Dingbats. A chart of Dingbats is given in table 6. See p. 8 for details of a package which lets you easily access this font.

If you buy other POSTSCRIPT fonts, you will find that you are supplied with the font itself and a font metric file. The latter can be converted to a T<sub>E</sub>X font metric file, and the font either downloaded permanently to a printer, or sent with every job. The details of this and beyond the scope of this guide, and you are advised to consult the support team.

## 7 Previewers

Previewing your output before printing can save lots of paper. There are two possibilities:

1. Use a dvi previewer. The recommended ones are *dvipage* for those using Sunview, and *xdvi* for those using X Windows. The former is fast, and has an excellent interface, but it does not support some of the more modern features of dvi drivers, and may not reproduce your output accurately (not at all if you use POSTSCRIPT fonts). The latter is rather more cumbersome, but has more features. In particular, it can access a set of bitmap versions of the common POSTSCRIPT fonts, which allows users of packages like ‘times’ to see exactly what they are getting. The manual pages for the two commands should be consulted for usage.
2. Neither of the previewers lets you see embedded POSTSCRIPT graphics, or effects like text rotation or gray shades. It is therefore often desirable to run the output through *dvips* (using the `-o` option to save the output) and use a POSTSCRIPT previewer. If you use Sun’s OpenWindows, this includes the *pageview* command to show any POSTSCRIPT file. The public domain Ghostscript (*gs*) is rather faster and more reliable, but has a poor interface. It is enhanced by the GhostView (*ghostview*) command which offers a good interface and calls on *ghostscript* to do the work.

## 8 Related software

There is a wide variety of supporting or related software available; a brief description is given below of commands which may be of interest. Unix manual pages are provided for all of these; note that you must add `/usr/local/man` to your *manpath* to access some of these:

**tex** Plain T<sub>E</sub>X.

The following commands are for serious T<sub>E</sub>Xnicians only:

**MakeTeXPK** used by dvips and xdvi to create new .pk files from font sources on demand

**afm2tfm** create .tfm files from Adobe .afm files

**dvicopy** take a .dvi file and resolve all virtual font references, and write a new .dvi file with the result

**dvitype** list a .dvi file in human-readable form for debugging

**gftodvi** convert .gf font file to .dvi form for printing

**gftopk** convert .gf font file to .pk form

**gftype** list a .gf font file in human-readable form

**initex** a special version of T<sub>E</sub>X which can read hyphenation patterns and write format files

**patgen** generate a T<sub>E</sub>X hyphenation file from list of hyphenated words

**pktogf** convert .pk font file to .gf form

**pktype** list a .pk font file in human-readable form

**pltotf** convert a .pl (human readable) font metric file to .tfm

**tangle** convert .web files to compilable Pascal

**ttotpl** convert a .tfm font metric file to .pl (human readable) form

**vftovp** convert .vf virtual font files to .vpl (human readable) form

**vptovf** convert .vpl (human readable) form virtual font files to .vf form

**weave** convert .web files to .tex files for printing

## A Joining the T<sub>E</sub>X and L<sup>A</sup>T<sub>E</sub>X Community

Thanks to the generosity of Don Knuth and Leslie Lamport, and contributions from many individuals around the world, T<sub>E</sub>X, METAFONT and L<sup>A</sup>T<sub>E</sub>X are available, and in the public domain, on machines ranging from microcomputers like the IBM PC and the Apple Macintosh, to large mainframes. Actual implementations of these programs usually cost some money, but only because a certain expenditure of human effort is required to prepare a smoothly-functioning installation.

There is a large and active T<sub>E</sub>X Users Group, TUG, which meets every summer, and which publishes an excellent quarterly journal, TUGBOAT, which averages about 200 pages per year. Membership in TUG costs only about \$50 a year, and order forms for membership, back issues, and other T<sub>E</sub>X publications are available from the T<sub>E</sub>X Users Group, P. O. Box 869, Santa Barbara, CA 93102, USA. Telephone 805-899-4673. Email (Internet) [tug@tug.org](mailto:tug@tug.org)

Immediately before and after the summer conference, there are workshops and tutorials for new, intermediate, and advanced users, and video tapes of several of them are available for rent or purchase through TUG. If sufficient local interest and support exists, TUG will also coordinate the holding of local on-site workshops to train people in the use of T<sub>E</sub>X and L<sup>A</sup>T<sub>E</sub>X.

## A.1 UK T<sub>E</sub>X users

The UK T<sub>E</sub>X Users Group offers a joint membership with international TUG, publishes a newsletter, and has regular workshop meetings. Mail `p.abbott@aston.ac.uk` for details. It is also closely associated with the UK T<sub>E</sub>X Archive at Aston University. This is a huge collection of T<sub>E</sub>X-related material which may have what you want. You can access it using *ftp* to site `ftp.tex.ac.uk` (134.151.40.18).

Local T<sub>E</sub>X users with access to Usenet news and becoming addicted to T<sub>E</sub>X should also read *comp.text.tex*, but be warned that this is a high-volume news group and can get quite technical.
